# Lecture 9b - Supervised Machine Learning II 

Jesse Hoey<br>School of Computer Science<br>University of Waterloo

June 27, 2022

Readings: Poole \& Mackworth (2nd ed.)Chapt. 7.3.2,7.5-7.6

## Linear Regression

Linear regression is a model in which the output is a linear function of the input features.

$$
\begin{aligned}
& \hat{Y}^{\vec{w}}(e)=w_{0}+w_{1} X_{1}(e)+\cdots+w_{n} X_{n}(e) \\
& \hat{Y}^{\vec{w}}(e)=\sum_{i=0}^{n} w_{i} X_{i}(e)
\end{aligned}
$$

where $\vec{w}=\left\langle w_{0}, w_{1}, w_{2} \ldots w_{n}\right\rangle$. We invent a new feature $X_{0} \equiv 1$, to make it not a special case.

## Linear Regression

Linear regression is a model in which the output is a linear function of the input features.

$$
\begin{aligned}
& \hat{Y}^{\vec{w}}(e)=w_{0}+w_{1} X_{1}(e)+\cdots+w_{n} X_{n}(e) \\
& \hat{Y}^{\vec{w}}(e)=\sum_{i=0}^{n} w_{i} X_{i}(e)
\end{aligned}
$$

where $\vec{w}=\left\langle w_{0}, w_{1}, w_{2} \ldots w_{n}\right\rangle$. We invent a new feature $X_{0} \equiv 1$, to make it not a special case.
The sum of squares error on examples $E$ for output $Y$ is:

$$
\begin{aligned}
& \operatorname{Error}(E, \vec{w})=\sum_{e \in E}\left(Y(e)-\hat{Y}^{\vec{w}}(e)\right)^{2} \\
& =\sum_{e \in E}\left(Y(e)-\sum_{i=0}^{n} w_{i} X_{i}(e)\right)^{2}
\end{aligned}
$$

Goal: find weights that minimize $\operatorname{Error}(E, \vec{w})$.

## Finding weights that minimize $\operatorname{Error}(E, \vec{w})$

Find the minimum analytically.
Effective when it can be done (e.g., for linear regression). If

- $\vec{y}=\left[Y\left(e_{1}\right), Y\left(e_{2}\right), \ldots Y\left(e_{M}\right)\right]$ is a vector of the output features for the $M$ examples
- $X$ is a matrix where the $j^{\text {th }}$ column is the values of the input features for the $j^{t h}$ example
- $\vec{w}=\left[w_{0}, w_{1}, \ldots, w_{n}\right]$ is a vector of the weights
then,

$$
\begin{aligned}
\vec{y}^{T} & =\vec{w} X \\
\vec{y}^{T} X^{T}\left(X X^{T}\right)^{-1} & =\vec{w}
\end{aligned}
$$

$\left(X X^{T}\right)^{-1}$ is the pseudo-inverse

## Finding weights that minimize $\operatorname{Error}_{E}(\vec{w})$

Find the minimum iteratively.
Works for larger classes of problems (not just linear). Gradient descent :

$$
w_{i} \leftarrow w_{i}-\eta \frac{\partial \operatorname{Error}(E, \vec{w})}{\partial w_{i}}
$$

$\eta$ is the gradient descent step size, the learning rate.
If

$$
\operatorname{Error}(E, \vec{w})=\sum_{e \in E}\left(Y(e)-\hat{Y}^{\vec{w}}(e)\right)^{2}=\sum_{e \in E}\left(Y(e)-\sum_{i=0}^{n} w_{i} X_{i}(e)\right)^{2}
$$

then update rule:

$$
w_{i} \leftarrow w_{i}+\eta \sum_{e \in E}\left(Y(e)-\sum_{i=0}^{n} w_{i} X_{i}(e)\right) X_{i}(e)
$$

where we have set $\eta \rightarrow 2 \eta$ (arbitrary scale)

## Incremental Gradient Descent for Linear Regression

1: procedure LinearLearner $(X, Y, E, \eta)$

2:
3:
4:
5:
6: $\quad$ initialize $w_{0}, \ldots, w_{n}$ randomly
7:
8:
9:
10 :
11:
12:
13: $Y$ : output feature
$\eta$ : learning rate
repeat
for each example $e$ in $E$ do
for each $i \in[0, n]$ do
until some stopping criteria is true
return $w_{0}, \ldots, w_{n}$

Inputs $X$ : set of input features, $X=\left\{X_{1}, \ldots, X_{n}\right\}$
$E$ : set of examples from which to learn

$$
\delta \leftarrow Y(e)-\sum_{i=0}^{n} w_{i} X_{i}(e)
$$

$$
w_{i} \leftarrow w_{i}+\eta \delta X_{i}(e)
$$

## Stochastic and Batched Gradient Descent

- Algorithm on the last slide is incremental gradient descent
- If examples are chosen randomly at line 8 then its stochastic gradient descent .
- Batched gradient descent:
- process a batch of size $n$ before updating the weights
- if $n$ is all the data, then its gradient descent
- if $n=1$, its incremental gradient descent
- Incremental can be more efficient than batch, but convergence not guaranteed

## Linear Classifier

- Assume we are doing binary classification, with classes $\{0,1\}$
- There is no point in making a prediction of less than 0 or greater than 1.
- A squashed linear function is of the form:

$$
\begin{aligned}
\hat{Y}^{\vec{w}}(e) & =f\left(w_{0}+w_{1} X_{1}(e)+\cdots+w_{n} X_{n}(e)\right) \\
& =f\left(\sum_{i=0}^{n} w_{i} X_{i}(e)\right)
\end{aligned}
$$

where $f$ is an activation function.

- A simple activation function is the step function :

$$
f(x)= \begin{cases}1 & \text { if } x \geq 0 \\ 0 & \text { if } x<0\end{cases}
$$

## Gradient Descent for Linear Classifiers

If the activation function is differentiable, we can use gradient descent to update the weights. The sum of squares error:

$$
\operatorname{Error}(E, \vec{w})=\sum_{e \in E}\left(Y(e)-f\left(\sum_{i=0}^{n} w_{i} * X_{i}(e)\right)\right)^{2}
$$

The partial derivative with respect to weight $w_{i}$ is:

$$
\frac{\partial \operatorname{Error}(E, \vec{w})}{\partial w_{i}}=-2 * \delta * f^{\prime}\left(\sum_{i} w_{i} * X_{i}(e)\right) * X_{i}(e)
$$

where $\delta=\left(Y(e)-f\left(\sum_{i=0}^{n} w_{i} X_{i}(e)\right)\right)$.
Thus, each example $e$ updates each weight $w_{i}$ by

$$
w_{i} \leftarrow w_{i}+\eta * \delta * f^{\prime}\left(\sum_{i} w_{i} * X_{i}(e)\right) * X_{i}(e)
$$

## The sigmoid or logistic activation function

## The sigmoid or logistic activation function

## Discussion Board Example

$$
\widehat{\operatorname{Reads}}(e)=\operatorname{sigmoid}(-8+7 * \operatorname{Short}(e)+3 * \operatorname{New}(e)+3 * \operatorname{Known}(e))
$$

Using the 18 training examples from lecture 4, this can be found in about 3000 iterations with a learning rate of $\eta=0.05$

## Linearly Separable

- A dataset is linearly separable if there is a hyperplane where the classification is true on one side of the hyperplane and false on the other side.
- The hyperplane is defined by where the predicted value, $f^{\vec{w}}\left(X_{1}, \ldots, X_{n}\right)=f\left(w_{0}+w_{1} X_{1}(e)+\cdots+w_{n} X_{n}(e)\right)$ is 0.5.
For the sigmoid function, the hyperplane is defined by $w_{0}+w_{1} X_{1}(e)+\cdots+w_{n} X_{n}(e)=0$.
- Some data are not linearly separable

## Kernel Trick

Some arbitrary data:

## Kernel Trick

Data is not linearly separable:

## Kernel Trick

Add another dimension, data is now linearly separable:

## Kernel Trick: another example

$$
\left(\frac{x_{1}}{a}\right)^{2}+\left(\frac{x_{2}}{b}\right)^{2}=1 \rightarrow \frac{z_{1}}{a^{2}}+\frac{z_{3}}{b^{2}}=1
$$

## Mercer's Theorem

Key idea:

- Mercer's Theorem
- A dot product in the new "lifted" space = function (kernel) in old space
- Means: never have to know what $\phi$ is!!
- Only have to compute distances with the kernel .

## Example

(

$$
\phi\left(x_{1}, x_{2}\right) \rightarrow\left(x_{1}^{2}, \sqrt{2} x_{1} x_{2}, x_{2}^{2}\right)
$$

dot product in old space:
$<x, w>=x_{1} * w_{1}+x_{2} * w_{2}$ dot product in new space:
kernel $K(x, w)$

$$
\begin{aligned}
K(x, w) & =<\phi(x), \phi(w)> \\
& =x_{1}^{2} w_{1}^{2}+2 x_{1} x_{2} w_{1} w_{2}+x_{2}^{2} w_{2}^{2} \\
& =\left(x_{1} w_{1}+x_{2} w_{2}\right)^{2} \\
& =(<x, w>)^{2}
\end{aligned}
$$

Circle data is linearly separable if distance (dot product) is computed using $K(x, w)$

## Support Vector Machines

find the classification boundary with the widest margin
0 : $c_{i}=-1$
x : $c_{i}=+1$
minimize $\|w\|^{2}$ subject to $c_{i}\left(w \cdot x_{i}-b\right)>1$
Quadratic Programming problem
Also: use Kernel trick

## Neural Networks

- inspired by biological networks (brain)
- connect up many simple units
- simple neuron: threshold and fire
- can help gain understanding of how biological intelligence works

## Neural Networks

- can learn the same things that a decision tree can
- imposes different learning bias (way of making new predictions)
- back-propagation learning: errors made are propagated backwards to change the weights
- often the linear and sigmoid layers are treated as a single layer

## Neural Networks Basics

- Each node $j$ has a set of weights $w_{j 0}, w_{j 1}, \ldots, w_{j N}$
- Each node $j$ receives inputs $v_{0}, v_{1}, \ldots v_{N}$
- number of weights $=$ number of parents +1

$$
\left(v_{0}=1 \text { constant bias term }\right)
$$

- output is the activation function output

$$
o_{j}=f\left(\sum_{i} w_{j i} v_{i}\right)
$$

necessarily non-linear because
A linear function of a linear function is a ...
linear function

## Neural Networks Basics

- activation functions:
- step function $=$ integrate-and-fire (biological)

$$
f(z)= \begin{cases}c & \text { if } z \geq 0 \\ 1 & \text { if } z<0\end{cases}
$$

- sigmoid function $f(z)=1 /\left(1+e^{-z}\right)$
- rectified linear (ReLU): $g(z)=\max \{0, z\}$
- output of entire network is the classification result

## Deep Neural Networks

output features
complete linear function
hidden layer
activation function
hidden layer
complete linear function
hidden layer
activation function
hidden layer

Fiqure 7.16: A deep neural network

## Learning weights

back-propagation implements stochastic gradient descent Recall:

$$
w_{i} \leftarrow w_{i}-\eta \frac{\partial E \operatorname{Error}(E, \vec{w})}{\partial w_{i}}
$$

$\eta$ : learning rate.
Linear unit:

$$
\frac{\partial(a w+b)}{\partial w}=a
$$

Sigmoid unit (chain rule):

$$
\frac{\partial f(g(w))}{\partial w}=f^{\prime}(g(w)) \frac{\partial g(w)}{\partial w}
$$

## Learning weights

Using the chain rule, this can be extended throughout the network e.g. taking a derivative of the $L^{\text {th }}$ layer w.r.t a weight in the $R^{t h}$ layer:

$$
\begin{aligned}
\frac{\partial \text { output }_{L}}{\partial w^{R}} & =\frac{\partial f\left(\text { output }_{L-1}\right)}{\partial w^{R}} \\
& =f^{\prime}\left(\text { output }_{L-1}\right) \frac{\partial \sum_{i} w_{j i}^{L-1} \text { input }_{L-1}}{\partial w^{R}} \\
& =f^{\prime}\left(\text { output }_{L-1}\right) \sum_{i} w_{j i} \frac{\partial f\left(\text { output }_{L-2}\right)}{\partial w^{R}} \\
& =f^{\prime}\left(\text { output }_{L-1}\right) \sum_{i} w_{j i} f^{\prime}\left(\text { output }_{L-2}\right) \ldots \frac{\partial \sum_{k} w_{l k}^{R} \text { input }_{R}}{\partial w^{R}} \\
& =f^{\prime}\left(\text { output }_{L-1}\right) \sum_{i} w_{j i} f^{\prime}\left(\text { output }_{L-2}\right) \ldots \text { input }_{R}
\end{aligned}
$$

## Backpropagation

back-propagation implements stochastic gradient descent

- each layer $i=1 \ldots L$ has:
- $N_{i}$ input units with input $[j], j=1 \ldots N_{i}$
- $M_{i}$ output units with output $[j], j=1 \ldots M_{i}$
- $Y[j]$ is the data output/labels (output [L])
- $X[i]$ is the data input (input[1])
- error on output layer unit $j$ : error $[j]=(Y[j]-$ output $[j])$
- for each other layer:

1. weight update (linear layer) $w_{j i} \leftarrow w_{j i}+\eta * \operatorname{input}[i] * \operatorname{error}[j]$
2. back-propagated error (linear layer) input_error $[i]=\sum_{j} w_{j i}$ error $[j]$
3. back-propagated error (activation layer) input_error $[i]=f^{\prime}($ output $[i]) * \operatorname{error}[i]$

## Backpropagation

## 1: repeat

2:
3:
4:
5:
6:
7:
8: until some stopping criteria is reached

## Regularization

Regularized Neural nets: prevent overfitting, increased bias for reduced variance

- parameter norm penalties added to objective function
- dataset augmentation
- early stopping
- dropout
- parameter tying
- Convolutional Neural nets: used for images
- Recurrent Neural nets: used for sequences

## Composite models

- Random Forests
- Each decision tree in the forest is different
- different features, splitting criteria, training sets
- average or majority vote determines output
- Ensemble Learning : combination of base-level algorithms
- Boosting
- sequence of learners
- each learner is trained to fit the examples the previous learner did not fit well
- learners progressively biased towards higher precision
- early learners: lots of false positives, but reject all the clear negatives
- later learners: problem is more difficult, but the set of examples is more focussed around the challenging boundary
